

ICP Scoring System, Build Phases

5 weeks, four phases, \$2,750 total.

Week 1: Foundation and Data Pulling

Get the plumbing in first: the database, login, and the connections to Creditsafe and Cognism. By the end of this week the app exists, you can sign in with a predefined account, and it can pull real data on a company without human help.

You'll be able to import a list of companies, hit run, and watch it pull financial and firmographic data automatically. No scoring yet, just proof the data pipeline works and doesn't double charge on a re-run.

Tools: Next.js, Supabase, Creditsafe API, Cognism API, n8n.

Week 3: Scoring and Classification

This is the brain of the tool. Every company gets sorted into a sector, then scored against whichever ICP you've chosen, with the weighting rules fully adjustable rather than baked into the code.

A company goes in, comes out the other side with a sector guess, a score, and a tier. Anything the system isn't confident about gets held back for a person to check rather than guessing.

Tools: Firecrawl, Exa, LLM classification (via OpenRouter), n8n scoring pipeline, Supabase config tables.

Week 4: The Screens People Actually Use

Now it gets a proper front door: the import screen, the ranked target list, the company detail view, and the contacts tool where you pick who to actually pay to unlock (email and phone).

Someone on the team can log in, import a list, see it scored and ranked, click into a company, and pull contact details for the people worth reaching, without touching a spreadsheet or a developer.

Tools: Next.js front end, Supabase (row-level security for roles), Cognism contact search and redeem.

Week 5: Accounts Module

Two things happen in parallel this week: a spend and usage dashboard, so nobody's guessing what this is costing, and the Accounts side, tracking companies once they've become paying clients, with manual ratings and a simple health score.

The client tracking piece is subject to Lignum's Loxo API, which hasn't been confirmed yet.

Tools: Supabase usage logging, analytics dashboards, notification system, Creditsafe monitoring feed.

Note: this assumes steady focus, one developer, and no major surprises from the four external services being pulled in. Real integrations always have a rough edge or two. If one shows up, it gets fixed in the week it's found rather than pushed to the end.
